Preface

- Audience
- Conventions
- Documentation Feedback
- Obtaining Documentation and Submitting a Service Request

This publication is for experienced network administrators responsible for configuring and maintaining network switches with some expertise in the following areas:

- Network administration
- OpenStack network administration
- Storage administration
- Server administration
- Application delivery administration
- Network security administration

Conventions

This document uses the following conventions:

Convention	Indication
Bold font	Keywords, user interface elements, and user- entered text appear in bold font.
Italic font	Document titles, new or emphasized terms, and variables that you supply values are in <i>italic</i> font.
[]	Elements in square brackets are optional.
$\{x y z\}$	Required elements are grouped in curly braces and are separated by vertical bars.
[x y z]	Optional parameters are grouped in brackets and separated by vertical bars.
String	A non-quoted set of characters. Do not use quotation marks around the string or the string includes the quotation marks.
courier font	Command Line Interface (CLI) commands and samples appear in courier font.
<>	Non-printing characters such as passwords are indicated by angle brackets.
[]	Default responses to system prompts are in square brackets.
:	Indicates that you enter the following text at the command prompt.

Note:	Indicates information of special interest.
Caution!	Indicates a situation that could cause equipment failure or loss of data.
TIP!	Indicates information that can help you solve a problem.
Warning:	Indicates information that could impact you or your network.
Time Saver:	Indicates information that can help you save time.

To provide technical feedback on this document, or to report an error or omission, please send your comments to: pln-doc-feedback@arista.com

We appreciate your feedback.

For information on obtaining documentation, submitting a service request, and gathering additional information, please visit www.pluribusnetworks.com.

Glossary of NetVisor UNUM and NetVisor OS Terms

To review the Glossary, refer to the online document.

Understanding the NetVisor OpenStack Neutron ML2 Plugin

OpenStack is a cloud operating system that can be deployed in both public and private clouds and it controls large pools of compute, storage, and networking resources throughout a datacenter. These resources are managed and provisioned through a dashboard, CLI, or through APIs with common authentication mechanisms.

NetVisor uses the OpenStack plugin mechanism to create a Layer 2 network (VLAN), the NetVisor Modular Layer 2 (ML2) plugin, which provides powerful and simplified overlay automation services, allows customers to create a network by configuring the VLANs and switch ports on NetVisor Unified Cloud Fabric over VXLAN tunnel or overlays. For details on Unified Cloud Fabric, see the *Configuring and Administering the Unified Cloud Fabric chapter* in the *Configuration Guide for NetVisor OS*.

The integration of NetVisor ML2 Driver Plugin with the OpenStack Architecture is explained below with the help of the topology diagrams. The networking (Neutron) component of OpenStack architecture is integrated through redundant programmable REST APIs to the NetVisor Unified Cloud Fabric (refer **Figure 1**).

OpenStack Architecture

Figure 1: Unified Cloud Fabric - OpenStack Integration

Further, the NetVisor ML2 driver plugin integrates with the Mechanism drivers running on the compute or network nodes of the OpenStack architecture and establishes communication between the Unified Cloud Fabric and the OpenStack Architecture (refer **Figure 2**).

The NetVisor OpenStack Neutron ML2 Plugin (cont'd)

Figure 2: NetVisor ML2 Driver Plugin Integration with Neutron (Networking) Server

As shown in *Figures 3*, the ML2 plugin uses the Pluribus REST APIs to configure the NetVisor switches. That is, the ML2 plugin running on the controller node interfaces with the REST APIs to configure the NetVisor switches in the fabric. For this deployment to work, you must configure a username/password in the ML2 config file on the OpenStack controller (triple 0, aka 0-0-0, which is OpenStack-on-OpenStack). These authentication credentials apply to all the switches on the fabric (that is, this is not on per tenant basis) and the credentials (password) is stored in an encrypted base64 format on the ML2 plugin.

The NetVisor Networks OpenStack Neutron ML2 Plugin (cont'd)

Figure 3: Integration of Unified Cloud Fabric with OpenStack Components using NetVisor ML2 Plugin

The NetVisor OpenStack Neutron ML2 Plugin (cont'd)

The NetVisor ML2 plugin, which provides powerful and simplified overlay automation services, enables seamless connectivity for east-west traffic between virtual machines (VMs) running on compute nodes that are connected to the Unified Cloud Fabric. The VLANs used by the VMs are configured across each cluster and the VLANs are stitched across the fabric using VXLAN tunnels (VXLAN overlays) by the ML2 plugin (refer **Figure 4**).

Figure 4: VXLAN Tunnel in Unified Cloud Fabric with OpeComponents

System Requirements and Guidelines

The following system requirements are needed to install and use the NetVisor ML2 plugin:

• Red Hat OpenStack Controller (TripleO deployment, a.k.a, OpenStack-On-OpenStack deployment) : Use any OpenStack controller running Queens release.

Note: The NetVisor features are validated on Red Hat Controller (Queens Release).

- Compute nodes
- Director (TripleO deployment)

Pre-Requisites:

- Enable Web server on the NetVisor switch, see details in the subsequent sections. You can verify if the web server is enabled or not by using the admin-service-show command on the NetVisor switch.
- Install and enable Link Layer Discovery Protocol daemon (LLDPd) on the compute and controller nodes. Use the IIdp-show command on the NetVisor switch to verify if all the host names are displayed.
- Configure a username/password in the ML2 config file on the OpenStack controller (triple 0). These authentication credentials apply to all the switches on the fabric (that is, this is not on per tenant basis) and the credentials (password) is stored in an encrypted base64 format on the ML2 plugin.

For more details, see the Configuring a Network using NetVisor ML2 Plugin section later in this document.

Usage Guidelines:

• While creating a VLAN network, the VXLAN network identifier (VNI) gets automatically chosen and populated by the ML2 plugin, which is in the format: 11million+ VLAN_ID.

Note: The VNI range, <11million+4K> is reserved for OpenStack networks and hence we recommend not to use the VLAN ID range of 4K as the VNI calculation is: 11million+ VLAN_ID.

• In NetVisor OS version 5.2, the NetVisor ML2 plugin supports cluster-based topologies with VXLAN tunnels established. Therefore, all Leaf switches must be part of a cluster in the fabric. That is, standalone switches are not supported by the ML2 plugin.

Downloading and Installing the NetVisor ML2 Plugin

Note: For details on installing the Red Hat controllers and platforms, refer to the Red Hat documentation:

The NetVisor ML2 plugin package is available as a Docker image, which you can download from GitHub. You must download the plugin package and install on the Red Hat OpenStack controller.

Installing the ML2 Plugin on a Red Hat Controller

To install the NetVisor ML2 plugin on a Red Hat Controller:

Based on the RedHat OpenStack Platform and NetVisor OS version, follow *step 1.1* if the plugin package image is available and you want to just pull the docker image from Docker Hub. Follow *step 1.2* if you want to build the docker image and then install the image on the controller.

- 1) To install the ML2 plugin :
 - 1.1. Download and install image from https://hub.docker.com/ for RedHat OpenStack Platform (TripleO).

Each repository's tag has the RedHat OpenStack version and the NetVisor OS (nvOS) version. For example, if the repository is:

pluribusnetworks/openstack-neutron-server-pn:13.0-105.1580118143-5.2.0, RedHat OpenStack version = 13.0-105.1580118143 and nvOS version = 5.2.0

then, download the docker image - docker pull pluribusnetworks/openstack-neutron-server-pn:13.0-105.1580118143-5.2.0

OR

1.2. Build the docker image from source:

- Obtain NetVisor ML2 plugin from Arista TAC
- Extract the tarbal of NetVisor ML2 plugin and cd to the directory that is extracted out of the tarbal and then do: cd networking-pluribus
- Build the RPM package: sudo python setup.py bdist_rpm #
- Change the directory to find networking-pluribus-<version>.noarch.rpm
- Change the directory back to PNopenstack/networking-pluribus
- Modify the Dockerfile to:

\$ cat Dockerfile
FROM <registry>/rhosp13/openstack-neutron-server<image>:<tag> ====> modify to the

current neutron server image MAINTAINER Pluribus Networks USER root RUN rpm -e networking-pluribus | echo "1" COPY dist/networking-pluribus-<version>.noarch.rpm /tmp =====> modify version to the one generated in dist/ RUN rpm -ivvh /tmp/networking-pluribus-<version>.noarch.rpm =====> modify version to the one generated in dist/ USER neutron

- Build a docker image: sudo docker build `pwd`
- Tag the image docker tag <IMAGE ID> pluribusnetworks/openstack-neutron-serverpn:13.0-105.1580118143-5.2.0
- 2) Tag and push 'pluribusnetworks/openstack-neutron-server-pn' to Local Registry

sudo docker tag <IMAGE ID> <Local-registry-IP: port>/rhosp13/openstack-neutron-server-pn:13.0-105.1580118143-5.2.0 sudo docker push <Local-registry-IP: port>rhosp13/openstack-neutron-server-pn:13.0-105.1580118143-5.2.0

3) Update DockerNeutronApilmage and DockerNeutronConfigImage in overcloud_images.yaml to the latest version of NetVisor OpenStack Plugin as suggested for that NetVisor OS version.

Edit overcloud_images.yaml to:

```
DockerNeutronApiImage: <Local-registry-IP: port>rhosp13/openstack- neutron-server-pn:13.0-
105.1580118143-5.2.0
DockerNeutronConfigImage: <Local-registry-IP: port>rhosp13/openstack- neutron-server-pn:13.0-
105.1580118143-5.2.0
```

- 4) Deploy the overcloud from the director node.
- 5) After the stack changes the status to UPDATE_COMPLETE, login to the overcloud and make changes suggested below:
 - 1) Edit entry_points.txt file from the location: /var/lib/config-data/puppetgenerated/neutron/etc/neutron/plugins/ml2/ [neutron.ml2.mechanism_drivers] pluribus = networking_pluribus.mech_driver.driver:PluribusMechanismDriver

For example: cd /usr/lib/python2.7/site-packages/neutron-12.0.5-py2.7.egg-info and Edit entry_points.txt.

2) Edit the /var/lib/config-data/puppet-generated/neutron/etc/neutron/plugins/ml2/ml2_conf.ini, add
 "pluribus" to mechanism drivers, and add the PLURIBUS_PLUGINS section:
 mechanism_drivers=openvswitch, baremetal, pluribus
 [PLURIBUS_PLUGINS]
 # Pluribus switch IP address
 #
 # pn_switch = 10.20.20.20:80,10.20.20.21:80

```
#
#
# Pluribus switch username and password for REST api access
#
# username = network-admin
#
# password = <base 64 encoded password>
```

The Format of specifying the Pluribus switch is: pn_switch, <primary_ip:web_port>,<secondary_ip:web_port>

Note: Because the NetVisor ML2 plugin uses RESTful APIs to configure the Unified Cloud Fabric, you must select two seed nodes in the fabric that can act as the primary node and the secondary node for the REST API to parse. Enter the management IP addresses of the selected seed nodes (primary and secondary) as the primary_ip and the secondary_ip respectively in the above configuration. Ensure to enter the IP addresses without giving space between primary IP address and secondary IP address as shown in the example above.

Note: You must enable web services on these selected (primary and secondary) nodes.

The web port for each switch can be obtained from the show output of the NetVisor OS CLI command, admin-service-show on the NetVisor switch. The web port can be any configurable port on the switch.

Note: The ml2_conf.ini and entry_points.txt are available in the path: /var/lib/config-data/puppet-generated/neutron/etc/neutron/plugins/ml2/ and are used by the neutron-server installed on the neutron_api docker container.

1. Restart *neutron-server* by restarting the docker container *neutron_api* using the command:

sudo docker restart neutron_api

2. Check the status of the docker image using the command:

```
sudo docker ps -a | grep neutron_api
```

For example,

[heat-admin@cloud-controller-0 neutron]\$ sudo docker ps | grep neutron_api 7cda7ac43cee 192.168.24.1:8787/rhosp13/openstack-neutron-server-pn-ml2:rev10 "dumb-init --singl..." About an hour ago Up About an hour (healthy) neutron_api [heat-admin@cloud-controller-0 neutron]\$ sudo docker stop neutron_api neutron_api [heat-admin@cloud-controller-0 neutron]\$ sudo docker start neutron_api neutron_api

For installation details on PackStack deployment, see the Appendix A- ML2 Plugin Installation: PackStack

Deployment section.

Note: As a network administrator, you must first provision and configure the NetVisor switch fabric. Use OpenStack to configure the NetVisor switch ports so that the VMs in the compute node sends east-west traffic through the NetVisor switch fabric.

Note: For details on the OpenStack configuration commands, see the OpenStack documentation from the Red Hat website or other vendor specific websites.

You can access the ML2 plugin and configure a VLAN network by using two methods: (1) using the OpenStack CLI commands and/or (2) using the Horizon Dashboard.

To configure a network:

Note: Enable web server on the NetVisor switches (the two seed nodes: primary and secondary) specified in the ml2_conf.ini file. Use the admin-service-show command on the NetVisor switch to verify if the web server is enabled or not.

1) Create the OpenStack network by using the OpenStack CLI command. For example, use the openstack network create <name> --provider-network-type vlan <segment id> command.

This command creates a VLAN network on the NetVisor switch and associates a VXLAN ID to the VLAN network. The VLAN ID is fetched from the OpenStack Neutron server and the corresponding VXLAN ID will be <11million + VLAN ID>. Then, the VXLAN network identifier (VNI) gets added to all the VXLAN Tunnel Endpoint (VTEPs), if configured on the switch fabric, or is added to all static tunnels. All the cluster ports also get added to the VLAN network.

2) Launch the VM instances by using the OpenStack CLI command, openstack server create. For example, openstack server create --image cirros --flavor ml.tiny --network test-network MyInstance.

Table - 1 Mapping actions of NetVisor ML2 plugin OpenStack commands on the NetVisor switch fabric:

OpenStack Commands/Actions	Mapping action on NetVisor switches
openstack network create	Creates a VLAN network with scope cluster on the NetVisor switch fabric and associates the VXLAN network ID (VNI) with the VLAN network, if configured.
openstack network delete	Deletes the previously configured VLAN network from the switch fabric.
	The ML2 plugin receives a port create/update request along with the hostname of the controller. The plugin fetches all the controller facing ports on the fabric and adds them to VLAN network.
	For example, to create a subnet 24, use the command:
openstack subnet create	[root@server-os-4 ~(keystone_admin)]# openstack subnet createsubnet-range 192.10.10.0/24 network <i>scorpius</i> subnet-1.
	Use the NetVisor OS command, lldp-show on the switch to verify the created/updated port details that got added to the VLAN network.
	See the <i>Related NetVisor OS CLI commands</i> section to view show output details.

Configuring a Network using NetVisor ML2 Plugin (cont'd)

OpenStack Commands/Actions	Mapping action on NetVisor switches
openstack server create	Note : Ensure to create the subnets before you execute the server create command. When a VM instance is launched, the NetVisor ML2 plugin receives port update request along with the
	binding host or the compute node details on which the VM is being spun. The ML2 plugin automatically detects all the host facing ports by using the LLDP information on the switch fabric and adds them to the VLAN network.
openstack server delete	When a VM instance is deleted, the ML2 plugin receives the port delete request and decides whether to remove switch ports from VLAN or not because multiple VM instances co-exist on the same compute node and in the same network. The host facing ports are removed from the VLAN only if it is the last instance that is being deleted.

Table - 1 Mapping actions of NetVisor ML2 plugin OpenStack commands (cont'd)

Table - 1 Mapping actions of NetVisor ML2 plugin OpenStack commands (cont'd)

OpenStack Commands/Actions	Mapping action on NetVisor switches
Alternatively, use the following commands to manu	ally add or delete ports later.
	Note : To add a host facing port to the VLAN network, use either of the two commands: openstack server create or openstack port create. When a port create/update request is received
	along with the binding host (compute node) information, the NetVisor ML2 plugin automatically detects all the host facing ports on the fabric and adds them to the VLAN received.
openstack port create	This is an optional command provided, if you want to configure the VLAN network for a particular host.
	For example, openstack port create test-porthost linux-host1network test-network.
	This command adds the correct switch ports to previously created VLAN for the compute node linux-host1. The ML2 plugin queries all the ports connected to the host linux-host1 by using the LLDP details and adds them to the VLAN network.
energtack port delete	Removes all the host facing ports from the VLAN if that is the last port being deleted as explained in openstack server delete command description.
obenergy hold detece	For example, the openstack port delete test-port command removes the port from the VLAN with which it was associated earlier.

Configuring a Network using NetVisor ML2 Plugin (cont'd)

Further to the OpenStack commands described in the table; below is an example of a sample configuration for creating a VLAN network on the OpenStack controller by using the ML2 plugin:

• Create an OpenStack network, scorpius with type, vlan and ID, 259 on the controller by using the OpenStack commands. The plugin programs VLAN 259 (example here) on all the cluster pair switches in the fabric.

[root@server-os-4 ~(keystone_admin)]# openstack network create scorpius --provider-network-type vlan -provider-physical-network physnet1 --provider-segment 259

[root@server-os-4 ~(keystone_admin)]#

• On the NetVisor switch, verify if a cluster scoped VLAN network is created and if the network has all the cluster scope ports within the VLAN by using the NetVisor OS CLI command:

switch id type vxlan auto-vxlan scope description active ports untagged-ports active-edge-ports sw-1 259 public 11000259 no cluster ostack-vlan-259 yes 0,27-30,272 none none sw1-1 259 public 11000259 no cluster ostack-vlan-259 yes 23-26,272 none none sw1-2 259 public 11000259 no cluster ostack-vlan-259 yes 23-26,272 none none sw2 259 public 11000259 no cluster ostack-vlan-259 yes 0,27-30,272 none none sw-2 259 public 11000259 no cluster ostack-vlan-259 yes 0,27-30,272 none none

CLI (network-admin@sw-1) > vlan-show id 259

Note: The VXLAN in the show output is of the range <11 million+VLAN ID>.

Configuring a Network using NetVisor ML2 Plugin (cont'd)

• Assign a Subnet, 192.10.10.0/24 to the previously created network, Scorpius on the controller:

[root@server-os-4 ~(keystone_admin)]# openstack subnet create --subnet-range 192.10.10.0/24 --network
scorpius subnet-1

[[]root@server-os-4 ~(keystone_admin)]#

• You can use the openstack network delete command to delete the previously created network or openstack port delete command to delete the ports.

After the above configurations are done, verify the details by using the NetVisor OS command, vlan-show id *259*:

CLI (network-admin@aq-os-2) > vlan-show id 259

switch	id	type	vxlan	replicators	scope	description	active	stats	ports		untag	ged-ports	active-edge-ports
aq-os-2	25	5 9 publ	ic 1100	0 259 none	c.	luster ostack-	-vlan-259	yes	no	0-2,27	-30,272-27	8 none	273
leo-os-1	259	public	: 11000259	none	cluste	r ostack-vlan	-259 yes	no	23-	-26,272		none	none
leo-os-2	259	public	: 11000259	none	cluste	r ostack-vlan	-259 yes	no	23-	-26,272		none	none
aq-os-1	25	9 publi	c 110002	59 none	clus	ter ostack-vl	lan-259 y	res	no	0-2,11	,27-30,272	-273 none	273

Note that in the above output, the VXLAN IDs corresponds to <11million+VLAN ID> and also the ports are added to the VLAN 259.

For more details on verifying the configurations using the corresponding NetVisor OS CLI commands, see the Related NetVisor OS CLI commands section.

Using the Horizon Dashboard to Configure a Network

In addition to using the OpenStack CLI commands, you can also use the Horizon dashboard to configure a VLAN network. Follow the steps below to create a network:

Refer to Red Hat OpenStack Horizon Dashboard for the latest and most updated user interface. The below screenshots are only for representative purposes.

1. On the Horizon dashboard, see below screen-shot to access the user interface:

BED HAT OPENSTACK	PLATFORM Project Admin Is	dentity					Project -	· Help <u>1</u> admin ~
Project - Co	ompute ~ Volumes ~	Network Coject Store						
Network Topology	Networks Routers	Security Groups Flo	ating IPs Trunk	ų.				
Project / Network /	Networks							
Network	s							
					Nome = +		Filter	+ Create Network
Name	Subnets Associated	Shared	External	Status	Admin State	Availability Zones		Actions
			No ite	ms to display.				
Q2								

2. To create a network using the dashboard:

Create Network	×
Network Subnet Subnet Details	Create a new network. In addition, a subnet associated
©~	with the network can be created in the following steps of this wizard.
 Enable Admin State Ø Shared Create Subnet Availability Zone Hints Ø 	
nova	
22.	Cancel « Back Next »

Using the Horizon Dashboard to Configure a Network (cont'd)

3. To create a subnet using the dashboard:

Create Network	24
Network Subnet Subnet Name subnet-1 Network Address ② 192.168.24.0/24 IP Version IPv4	Creates a subnet associated with the network. You need to enter a valid "Network Address" and "Gateway IP". If you did not enter the "Gateway IP", the first value of a network will be assigned by default. If you do not want gateway please check the "Disable Gateway" checkbox. Advanced configuration is available by clicking on the "Subnet Details" tab.
Gateway IP @	3
192.168.24.1	
Disable Gateway	
	Cancel « Back Next »

4. To create a VM instance using the dashboard:

RED HAT OPE	ISTACK PLATFORM	Project Admin	Identity								Project	- Help	1 admin ~

Inst	ance Name	Image Name	IP Address	Flavor	Key Pair	Status	Availability Z	one	Task	Power State	Time since created	Act	tions
						No items to o	display.						
	*												

Guidelines, Errors, and Exceptions

The following is a list of guidelines, limitations and exceptions to keep in mind while using the NetVisor ML2 plugin with the OpenStack deployment:

- Vendor/versions of supported OpenStack: The NetVisor ML2 plugin is supported on OpenStack Queens release and with RedHat OpenStack 13.0 distro. However, the ML2 plugin is generic and may be compatible with later releases also.
- **Supported deployment models of OpenStack**: The ML2 plugin package is available from GitHub based on the OpenStack controller implementation. For Red Hat OpenStack controller, the ML2 plugin is packaged as a *Docker* image. For other controllers, the plugin can be downloaded from Git Hub.
- **Pre-requisites** on NetVisor switches before creating on OpenStack node:
 - o Configure all the host (compute/controller) facing ports as edge ports
 - o Configure leaf clusters
 - o Create VTEP and ensure auto-tunnels are created or create static tunnels.
- **Configurations required on NetVisor switch before using OpenStack** : You must first create the VTEPs (which in turn creates the auto-tunnels) or static tunnels on the NetVisor switch fabric.
- VLAN vs VXLAN provisioning: When you configure a VLAN network using the openstack network create command, the ML2 plugin creates the VLAN and assigns a VNI from a predefined offset (11million). The VNI is added to all the VTEPs or static tunnels. The VLANs used by the VMs running on the compute nodes are configured on the NetVisor fabric by the ML2 plugin. The ML2 plugin adds or removes the VNI to the tunnel.

Note: NetVisor ML2 plugin supports only VLAN-type network. Requests for other network types such VXLAN, Flat, and GRE will fail to create.

• **Supported OpenStack controllers**: The ML2 plugin for Netvisor version 5.2.0 supports Red Hat OpenStack controller. However, the ML2 plugin is generic and should work with Ubuntu OpenStack controllers also.

Below is a list of error messages and exceptions to check for while configuring a VLAN network:

- All the errors are logged in /var/log/container/neutron/server.log for Red Hat OpenStack controller (overcloud) and in /var/log/neutron/server.log for other OpenStack deployments.
- Errors that you may encounter while creating an OpenStack network by using the openstack network create command:
 - If a VLAN already exists on the fabric, the ML2 plugin displays an error message: Vlan <vlan-id> already exists on fabric.
 - If a VXLAN is already in use, that is, if the VNI selected for a VLAN is already used by another VLAN in the fabric, an error message: *vxlan <vni> already in use* is displayed.
 - If there are no VTEPs or static tunnels configured on the switch fabric, an error message: Vlan create failed: vtep and tunnels not present on the switch fabric is displayed.
- Error messages you may encounter while deleting an OpenStack network by using the openstack network delete command.
 - If the VLAN does not exist on the cluster switch, an error message: VLAN <vlan-id> does not exist in switch <switch name> is logged in server.log file. However, the ML2 plugin deletes the VLAN on other clusters and does not display any failure messages.
- Errors displayed while creating an openstack port create and launching an instance:
 - No switch port found for host <hostname>: When a port create/update request is received by the plugin along with the binding host details, the plugin finds the host facing ports by using the lldp-show command on NetVisor switch. If no host facing ports are found, an error message: No switch port found for host <hostname> is displayed. The openstack port create command is executed only if the ML2 plugin can find at least one switch port for the host.
 - When some host facing ports are down, those ports are not displayed in the lldp-show command output and are not added to the VLAN. The ML2 plugin runs a daemon thread to periodically monitor ports table and checks for missing ports that were not added to the VLAN by comparing the lldp-show command output. When the port is back up and appears in the lldp-show command output, then the daemon thread adds the ports to the VLAN.
- Other errors:
 - If the switch fails to configure the fabric for any reason and returns an error, then the plugin raises an exception with a failure message in the REST API response.
 - If both the primary and secondary IP addresses specified in *ml2_conf.ini* file are unreachable during the configuration, the plugin displays an error message: The switches <switch name> are offline.

You can verify the mappings of OpenStack configurations on the NetVisor switch fabric by using the following NetVisor OS CLI commands:

- admin-service-show
- cluster-show
- lldp-show
- vlan-show

For example, below is a sample output for the admin-service-show command to check the web ports:

CLI (network-admin@switch-2) > admin-service-show

SWILCH-Z	udid	011	OII OII	011	440	00	OIL	011	011	
switch-1	mgmt	on	off on	off	443	80	off	off	on	
switch-1	data	on	off on	off	443	80	off	off	on	

CLI (network-admin@aq-os-2) > cluster-show

To change the web port details, use the admin-service-modify if mgmt web command:

CLI (network-admin@switch-2) > admin-service-modify if mgmt web

After you run the openstack network create command, verify the configuration on the NetVisor switch by using the cluster-show command. The cluster ports are added to the VLAN network.:

switch name state cluster-node-1 cluster-node-2 tid mode ports remote-ports cluster-sync- cluster-syncoffline-count leo-os-1 Cluster-leo-os online leo-os-1 leo-os-2 8075 slave 23-26,272 23-26,272 2000 3 leo-os-2 Cluster-leo-os online leo-os-1 leo-os-2 8075 master 23-26,272 23-26,272 2000 3 aq-os-2 Cluster-aq-os online aq-os-2 aq-os-1 7968 slave 27-30,272 27-30,272 2000 3 After you run the openstack subnet create command, verify using the lldp-show command along with the controller node details on the switch:

CLI (network-admin@aq-os-1) > lldp-show sys-name server-os-4.pluribusnetworks.com

switch	local-port	chassis-id	port-id	port-desc sys-n	name
aq-os-1	. 1	0c:c4:7a:6c:5c	:52 00:12:c0:88:0	c:36 enp4s0f0	server-os-4.pluribusnetworks.com
aq-os-1	. 2	0c:c4:7a:6c:5c	:52 00:12:c0:88:0	c:37 enp4s0f1	server-os-4.pluribusnetworks.com
aq-os-1	. 11	0c:c4:7a:6c:5c	:52 Oc:c4:7a:6c:5	c:53 eno2	server-os-4.pluribusnetworks.com
aq-os-2	1	0c:c4:7a:6c:5c	:52 00:12:c0:88:0	c:38 ens73f0	server-os-4.pluribusnetworks.com
aq-os-2	2	0c:c4:7a:6c:5c	:52 00:12:c0:88:0	c:39 ens73f1	server-os-4.pluribusnetworks.com

In the above output, *server-os-4.pluribusnetworks.com* is the controller name and all the above ports are added to the VLAN network (VLAN 259 in this example). Verify using the vlan-show id *259* command:

CLI (network-admin@aq-os-2) > vlan-show id 259

switch	id	type	vxlan	replicators	scope	description	active st	ats po	rts	untag	ged-ports	active-edge-ports
aq-os-2	259	public	: 110002	59 none	cluste	er ostack-vlan	-259 yes	no	0-2,27-	30,272-273	none	273
leo-os-1	259	public	1100025	9 none	cluster	ostack-vlan-2	59 yes	no	23-26,272		none	none
leo-os-2	259	public	1100025	9 none	cluster	ostack-vlan-2	59 yes	no	23-26,272		none	none
aq-os-1	259	public	c 110002	59 none	clust	er ostack-vla	n-259 yes	no	0-2,11	,27-30,272	-273 none	273

After you run the OpenStack server/port create, verify using the lldp-show command along with the compute node details on the switch:

CLI (network-admin@aq-os-1) > lldp-show sys-name server-os-9.pluribusnetworks.com

switch	local-port	chassis-id	port-id	port-desc sys-name	
leo-os-1	. 18	40:8d:5c:d	6:20:e3 00:12:c0:8	30:30:23 enpls0f1	server-os-9.pluribusnetworks.com
leo-os-2	18	40:8d:5c:d	6:20:e3 00:12:c0:8	80:30:22 enpls0f0	server-os-9.pluribusnetworks.com

In the above output, server-os-9.pluribus networks.com is the compute node name and the above ports are added to the VLAN network (VLAN 259 in this example). Verify using the vlan-show id 259 command:

CLI (network-admin@aq-os-2) > vlan-show id 259

switch	id	type	vxlan	replicators	scope	description	active st	ats po:	rts	untagged-ports	active-edge-ports
aq-os-2	259) publi	c 110002	59 none	clus	ster ostack-vlan	-259 yes	no	0-2,27-30,272-2	273 none	273
leo-os-1	259	public	1100025	9 none	clust	er ostack-vlan-2	259 yes	no	18,23-26,272	none	18
leo-os-2	259	public	1100025	9 none	clust	er ostack-vlan-2	259 yes	no	18,23-26,272	none	18
aq-os-1	259	9 publi	c 110002	59 none	clu	ster ostack-vla	n-259 yes	no	0-2,11,27-30,2	272-273 none	273

For details on the above NetVisor OS commands, see the *Configuration Guide for NetVisor OS* and *Command Reference Guides for NetVisor OS* from the **Pluribus Networks** website.

Appendix A- ML2 Plugin Installation: PackStack Deployment

For details on installing PackStack deployment, refer to PackStack page: https://www.rdoproject.org/install/packstack/

To download, install, and configure the NetVisor OpenStack ML2 plugin:

- 1. Install the NetVisor ML2 Plugin package on to a RedHat Openstack Controller:
 - a) Obtain NetVisor ML2 plug in from Arista TAC
 - b) Extract the tarbal of NetVisor ML2 plugin and cd to the directory that is extracted out of the tarbal and then do: cd networking-pluribus
 - c) sudo python setup.py install
- 2. Edit entry_points.txt file in neutron.egg-info
 [neutron.ml2.mechanism_drivers]
 pluribus = networking_pluribus.mech_driver.driver:PluribusMechanismDriver

For example:

```
pip show neutron
cd /usr/lib/python2.7/site-packages/neutron-12.0.5-py2.7.egg-info
Edit entry_points.txt
```

3. Edit the /etc/neutron/plugins/ml2/ml2_conf.ini, add "pluribus" to mechanism drivers, and add the PLURIBUS_PLUGINS section: mechanism_drivers=openvswitch, baremetal, pluribus

```
[PLURIBUS_PLUGINS]
# Pluribus switch IP address
#
# pn_switch = 10.20.20.20:80,10.20.20.21:80
#
# Pluribus switch username and password for REST api access
#
# username = network-admin
#
# password = <base 64 encoded password>
```

The Format of specifying the NetVisor switch is: pn_switch, <primary_ip:web_port>, <secondary_ip:web_port>

Note: Because the NetVisor ML2 plugin uses RESTful APIs to configure the Unified Cloud Fabric, you must select two seed nodes in the fabric that can act as the primary node and the secondary node for the REST API to parse. Enter the management IP addresses of the selected seed nodes (primary and secondary) as the primary_ip and the secondary_ip respectively in the above configuration. Ensure to enter the IP addresses without giving space between primary IP address and secondary IP address as shown in the example above.

Note: You must enable web services on these selected (primary and secondary) nodes.

The web port for each switch can be obtained from the show output of the NetVisor OS CLI command, admin-service-show on the NetVisor switch. The web port can be any configurable port on the switch.

Note: The ml2_conf.ini and entry_points.txt are available in the path: /var/lib/config-data/puppet-generated/neutron/etc/neutron/plugins/ml2/ and are used by the neutron-server installed on the neutron_api docker container.

1. Restart neutron-server service:

sudo systemctl restart neutron-server

2. Check the Neutron logs and verify the status of neutron-server service from: /var/log/neutron/server.log

sudo systemctl status neutron-server

Note: Adding the pluribus keyword to the ml2_conf.ini file ensures the Neutron server to fetch NetVisor ML2 driver while configuring the network.
